

AI-Native Financial Review Challenge

Build a working financial product that turns raw bank transactions into an explainable financial review.

The challenge

Build an AI-native Financial Review application using the provided bank transaction dataset. The application should understand and categorize transactions, calculate a monthly P&L, identify material variances, surface items requiring judgment, and let a user investigate the results through conversation.

Core workflow: ingest, categorize, review, calculate, explain, investigate.

What the application must do

1. Ingest financial data

Accept the provided bank transaction file as input. Parse the transactions and create a structured representation that can be used across the application.

2. Categorize and label transactions

Automatically classify transactions into sensible accounting categories. The user must be able to:

- See the category assigned to each transaction.
- Identify transactions where the system is uncertain.
- Correct an incorrect classification and save the correction.
- Distinguish transactions that belong in the P&L from transactions that may require different accounting treatment.

3. Build the P&L

Generate monthly P&Ls from the classified transactions. At minimum, show:

- Revenue
- Cost of Goods Sold

- Gross Profit
- Payroll
- Operating Expenses
- Operating Profit

The P&L must be calculated from the underlying transaction data. An LLM must not generate financial totals.

4. Find and explain variances

Compare monthly P&Ls and automatically identify material changes between periods. For important variances, explain what changed and identify the transactions or categories driving the change. The user should be able to move from a variance to its underlying evidence.

5. Identify items requiring review

Surface transactions where classification is uncertain, accounting treatment requires judgment, data appears unusual or inconsistent, or human review would be appropriate. The user must be able to review and resolve these items.

6. Build an AI financial analyst

Provide a conversational interface for investigating the financial data. The analyst should answer questions using the underlying structured data and provide traceable evidence where appropriate.

- What was our revenue in March?
- How much did we spend on payroll each month?
- Why did operating profit change between February and March?
- What drove the increase in food costs?
- Which transactions need my attention?
- Show me the transactions behind that variance.
- What changed most significantly over the review period?

AI-native engineering

This should be an AI-native application, not a conventional dashboard with a chatbot added to it. Use AI where reasoning, interpretation, or understanding is valuable. Use deterministic computation where financial accuracy is required.

- Where and why AI is used.
- Where and why deterministic logic is used.
- How incorrect or unsupported financial answers are prevented.
- How the system output is verified.

Technical freedom

You may choose the implementation that best supports a reliable, explainable product. These decisions are part of the challenge.

AREA	EXAMPLES
Application	Frontend, backend, database, deployment
AI system	Model, agent architecture, tools, categorization, retrieval
Financial logic	Chart of accounts, variance methodology, review rules

Using AI to build

You may use Claude Code, Codex, Cursor, Copilot, ChatGPT, or other AI development tools. You are responsible for understanding, testing, and being able to defend everything you submit.

Submission

- GitHub repository.
- Live deployed application.
- Video walkthrough.
- README with setup instructions and key technical decisions.

The walkthrough should demonstrate the end-to-end workflow:

- File ingestion.
- Transaction categorization.
- A classification correction.
- Generated P&L.

- A material variance and its drivers.
- At least two questions answered through the AI interface.
- How an answer or variance can be traced to its underlying data.

Shortlisted candidates will be invited to an in-person build session and interview in Koramangala, Bangalore.
